# 1996 TRANSPORTATION TOMORROW SURVEY DISCRETIONARY TRAVEL 

Data Management Group<br>Joint Program in Transportation<br>University of Toronto

January 1999

Prepared by Peter Dalton

## Executive Summary

Discretionary travel is defined as all trips other than home-based work and home-based school. For the purpose of this report discretionary trips are divided into three sub-categories - home-based shopping, home-based other and non home-based. The definition of a home-based trip is one that either starts or finishes at home. This report addresses three topics:

- The under reporting of discretionary travel in the 1996 TTS and the appropriate methods of correction.
- The analysis of discretionary trips and trip making characteristics.
- Issues that need to be addressed with respect to the formulation of p.m. peak period and 24hour travel demand models.

It is concluded that the primary source of under reporting in the TTS stems from the use of third-party respondents to report the trips made by other household members. Previous studies have established that home-based work and school trips are reported with a high degree of accuracy for both respondents and other household members. Under reporting of discretionary travel is significant with respect to both auto driver and public transit trips.

The use of the following factors is recommended to correct for under reporting caused by the use of thirdparty respondents:

|  | Auto Driver | Public Transit <br> (Excl. GO Train use) |
| :--- | :---: | :---: |
| Home-based Shopping | 1.34 | 1.39 |
| Home-based Other | 1.27 | 1.31 |
| Non Home-based | 1.41 | 1.36 |
| Combined totals | 1.33 | 1.34 |

There is no evidence of any under reporting of auto passenger trips in the TTS database. Discretionary travel is of minor importance with respect to GO Train operations accounting for $12 \%$, or less, of daily trips.

The adjustment factors may be applied to most subsets of the TTS data after extraction from the TTS database. The adjustment made to auto driver trips give daily traffic volumes which, in total, are 5\% to $10 \%$ less than observed cordon counts. It is not possible to say if this difference is due to other sources of under reporting, traffic that is not represented in the TTS or problems in the method of comparison. There is no valid basis for making further adjustment.

Discretionary travel in the GTA and Hamilton-Wentworth is estimated at $64 \%$ of total daily auto driver trips and $34 \%$ of the trips made by public transit excluding GO Train use. The characteristics of discretionary travel are such that these proportions will likely increase in the future. Discretionary travel volumes are significant between the hours of 7:30 a.m. and 10.30 p.m.

Trip generation rates based on TTS data, adjusted to correct for under reporting, should produce peak hour traffic volumes that are $10 \%$ to $15 \%$ higher in the afternoon than in the morning. The afternoon peak also extends over a longer period of time. Simulations of the p.m. peak period are likely to be more complex than the a.m. peak, because of the greater diversity of trip characteristics, but other factors are identified which favour simulation of the p.m. peak period. As a result it should be possible to develop a p.m. peak period model that is at least as reliable and robust as the current a.m. peak models. Chapter 5 contains suggestions as to how both the Full and Simplified GTA modelling procedures might be modified to produce p.m. peak and 24 -hour simulations.

### 1.0 Introduction

Extensive analysis and validation of the TTS data from 1986, 1991 and $1996^{1}$ have produced no evidence of any under reporting, or other biases, with respect to work and school trips. Comparisons with census data, cordon counts, GO Transit surveys and other transit ridership counts provide a close match to the TTS data with respect to total population, employment and travel by all modes in the a.m. peak period.
Differences of $25 \%$ to $30 \%$ between total daily travel reported in the TTS compared to cordon counts imply that off-peak road travel could be under reported by as much as $50 \%$. These differences need to be explained and accounted for if the TTS data is to be used in the estimation of off-peak and total daily travel.

The scope of this report, and the analysis contained in it, is restricted to the Greater Toronto Area (GTA) and the Regional Municipality of Hamilton-Wentworth. The 1996 TTS covered a larger geographic area but the data for areas external to the GTA and Hamilton-Wentworth have been excluded both in the calculation of correction factors and the subsequent analysis. The few exceptions are noted in the related text.

### 1.1 Under Reporting of Non Respondent Trips

The TTS methodology relies on the ability of a single member of each household, the respondent (also referred to as the informant in other studies), being able to accurately report the trip movements of all members of the household on the previous day. Figure 1.1 compares the average reported daily trip rates for respondents and non respondents. The comparison is based on persons 11 and older and shows the daily trip rates for the three sub categories (home-based shopping, home-based other and non home-based) of discretionary travel used in this report. Discretionary travel, by definition, excludes home-based work and home-based school trips. The lower trip rates reported for non respondents is a major factor in the apparent under reporting of trips in the TTS database relative to observed traffic and transit ridership counts. Some of the difference in reported trip rates may be due to differences in the sample population between respondents and non respondents. It is essential that differences in sample population be identified and taken into account before adjustments are made to correct for under reporting. Analysis of the 1986 TTS data by Hassounah and Cheah ${ }^{2}$ resulted in the recommended correction factors shown in Table 1.1(a). These correction factors, when applied to the subset of trips made by non respondents, produce the same overall trip rate as in the same subset for respondents

Figure 1.1 - Difference Between Respondent and Non Respondent Reported Daily Trip Rates - 1996 TTS Persons 11 \& Older

[^0]
## Table 1.1(a) - Trip Rate Correction Factors - 1986 TTS (Hassounah and Cheah)

| Type of trip | Household size | Correction <br> Factor |
| :--- | :--- | :--- |
| Non home-based auto trips < 5km | All | 3.134 |
| Home-based non work, non school <br> auto trips < 5 km | 2 persons | 1.404 |
|  | 3 persons | 2.142 |
|  | $4-5$ person | 2.780 |
|  | $>5$ persons | 3.625 |
| Home-based non work, non school <br> transit trips < | 2 km | 3 persons |
|  | $4-5$ person | 1.502 |
|  | $>5$ persons | 2.018 |

A similar analysis of the 1996 TTS data by Badoe ${ }^{3}$ resulted in the recommended correction factors shown in Table 1.1(b). The results are similar in that they show it is primarily short trips by automobile and local transit that are under reported. The 1986 analysis did not distinguish between auto driver and auto passenger trips whereas the 1996 analysis showed that it is predominantly auto driver trips that are under reported.

Applying correction factors to the trips recorded for non respondents is only one of several methods of correcting for under reporting of non respondent trips. A second method is to apply the correction factors to all the reported trips in a defined subset - not just the trips made by non respondents. A third approach is to expand the data for respondents to match the population of the total survey. A fourth approach would be to do a supplemental survey of non respondents. Each of these approaches has its strengths and weaknesses. There is no "right" or "wrong" method.

It can be argued that applying correction factors to the non respondent trip data is likely to provide for the most accurate spatial distribution of adjusted trip data. Conversely the method probably offers the greatest potential for distortion of other trip making characteristics. The stratification used to identify the subsets to which correction factors are applied must reflect both differences in the survey population (respondents vs. non respondents) that have different trip rates as well as differences in the level of under reporting. The number of factors and combinations of factors that can be included is severely limited by the amount of data available. The problem is further complicated by the inter-dependence of attributes and the need to pre-stratify continuous variables, such as trip maker's age, trip length and trip start time, into discrete intervals.

It was decided that the objectives of this study would more likely be achieved by only using the discretionary trip data collected from respondents. The approach taken was therefore to expand the data collected from respondents to represent the total population of the survey. It must be recognized at the outset that survey respondents do not constitute a random selection of trip makers. The expansion process, described in Section 1.3, corrects for obvious differences in the overall distribution of household size, age, gender and driver's license status but there are many other potential sources of bias. Chapter 2 provides comparisons made between the expanded respondent data, the original TTS data and independent count information. The analysis leads to the conclusion that the use of respondents to report non respondent trip information is the major cause of under reporting of trip data in the TTS.

The second method described above, i.e.- application of correction factors to global subsets, also has its advantages. The required correction factors can be applied to complete trip tables after they have been extracted from the TTS database. The required adjustments are smaller in relative magnitude offering less potential for creating anomalies associated with single records. Chapter 3 contains recommendations as to the correction factors that should be used.

[^1]Table1.1(b) - Trip Rate Correction Factors - 1996 TTS (Badoe)

| Trip | Trip | Mode | License | Start | Vehicles | Gender | Adj. | Resp. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  |  |  |  | 3:30-6:30 |  |  | 2.025 | 0.056 |
|  |  |  |  | 6:30-9 pm |  |  | 2.001 | 0.017 |
|  | Short | Transit | All | 6-9 am | $\begin{aligned} & 0 \\ & 1 \\ & 1 \\ & 2+ \end{aligned}$ |  | 4.082 | 0.0029 |
|  |  |  |  |  |  |  | 1.117 | 0.0007 |
|  |  |  |  |  |  |  | 1.379 | 0.0004 |
|  |  |  | Yes | 9-3.30 | all |  | 3.248 | 0.006 |
|  |  |  | No |  |  |  | 3.431 | 0.022 |
|  |  |  | All | 3:30-6:30 | 0 |  | 2.030 | 0.022 |
|  |  |  |  |  | 1 |  | 1.288 | 0.005 |
|  |  |  |  |  | 2+ |  | 1.078 | 0.0015 |
|  |  |  |  | 6:30-9 pm | 0 |  | 2.691 | 0.005 |
|  |  |  |  |  | 1 |  | 1.281 | 0.001 |
|  |  |  |  |  | 2+ |  | 1 | 0.0001 |

* Non respondent trip rate higher than respondent - No adjustment recommended

The use of supplemental surveys to fill in data gaps, or to obtain more accurate measurement of non response rates, has been tried in other surveys with limited success. The TTS trip diary survey in 1986 is one example. Supplemental surveys are time consuming and costly - clearly not an option for this study.

### 1.2 Differences in Respondent and Non Respondent Populations

The most obvious difference between respondent and non respondent population is in household size distribution. One hundred percent of 1-person households are, of necessity, survey respondents, $50 \%$ of 2person households, one third of 3-person households, etc. Figure 1.2(a) compares the age distribution of the survey respondent population with that of non respondents. Not surprisingly there is a significant difference with respect to the younger age groups with a negligible number of respondents below the age of 13. Figure 1.2 (b) shows the ratio of survey respondents to total population by age and gender. There is a higher proportion of women than men respondents in all age groups, predominantly so in the older age groups. The highest probability of a survey participant being a respondent occurs in the 83 to 87 age group as a result of household size distribution. Figure 1.2(c) shows that the majority of people over the age of 60 live in 1- and 2-person households and are therefore more likely to be survey respondents than those living in larger households. The number of elderly respondents living in large households is small.

Figure 1.2(a) - Age Distribution of Respondent \& Non Respondent Populations

Figure 1.2(b) - Ratio of Respondents to Total Survey Population by Age \& Gender

Figure 1.2(c) - Proportion of Survey Population Living in 1- and 2-person Households

Subsequent analysis also revealed that female respondents are more likely to be licensed to drive than are female non respondents. The apparent difference appears to be independent of age and household size.

### 1.3 Expansion of Respondent Data to Represent the Total Survey Population

Table 1.3(a) shows the factors used to expand the respondent trip data to represent the total population of the TTS survey. The factors have been calculated by dividing the expanded total TTS population in each category by the expanded number of respondents in the same category. The factors are multiplied by the existing expansion factor for each person in that category. The combined factor is used as the expansion factor for all of the discretionary trips made by that person. The expansion factors for discretionary trips made by non respondents in that same category are set to zero.

The adjustments are not applied to home-based work or home-based school trips because there is no evidence to suggest that these trips are under reported. Modifying the expansion factors for work and school trips, together with the exclusion of non respondent data, would almost certainly result in a deterioration in the quality of the data for those two categories. The expansion factors for discretionary trips made by persons for which the age question was refused, those under the age of 18 , those 78 and older living in 3-person households or aged 63 and older living in households of four persons or more, are not modified. There is insufficient respondent data in these categories to generate reliable factors. In addition it would seem likely that there could be significant genuine differences in travel behaviour between respondents and non respondents in these categories, particularly the elderly. With no valid basis on which to make adjustments it was considered best to leave the factors unchanged. The total number of trips in these categories is small accounting for $3 \%$ of total survey trip records.

The adjustment factors have been calculated using the data for residents of the GTA and HamiltonWentworth but have been applied to all survey records to facilitate the calculation of external trip generation rates and trip data if required. A person database, containing the revised expansion factors, has been created for the purpose of calculating discretionary trip rates. The expansion factors in both the trip and person databases have been rounded to one decimal place instead of the two decimal places used for the original TTS data. The change in rounding is not likely to produce any measurable difference in tabulated results. Table $1.3(\mathrm{~b})$ provides a summary of the number of records with non-zero expansion factors in the modified databases.

Table 1.3(a) - Expansion Adjustment Factors

| Male | Number of persons 16 or older in household |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| age | , | 2 | 3 | 4 | $5+$ |

Table 1.3(b) - Number of Records in the Modified Database

|  | Respondent database | Original TTS database |
| :--- | :---: | :---: |
| Person records | 193,736 | 312,781 |
| Non transit trip records | 460,863 | 587,676 |
| Transit trip records | 65,584 | 70,295 |
| Min. expansion factor | 11.1 | 11.10 |
| Max. expansion factor | 326.8 | 82.56 |

### 1.4 Validation of Expansion Process

The expansion process adjusts for biases in the selection of respondents that relates solely to age, gender and household size. There are other factors, including attributes not in the TTS database, that might affect the probability of a person becoming a survey respondent. Tables 1.4(a) and 1.4(b) compare the expanded

## Table 1.4(a) - Age Distributions - TTS \& Respondent Databases

| age | TTS | Resp. | Difference |  | age | TTS | Resp. | Difference |  |

totals from the respondent database with those from the original TTS database for selected person attributes. Significant differences could be an indication of uncorrected biases in the respondent database.

The age distribution of the respondent database has less pronounced peaks on the 10 year increments (30, $40,50,60,70,80$ and 90 ) suggesting that respondents are less likely to round their own age than they are the reported ages of other household members. If that is the correct explanation the respondent database may be the more precise of the two.

## Table 1.4(b) - Distribution of Person Attributes - TTS \& Respondent databases

The gender and household size distribution are almost identical, as would be expected given the expansion procedure. There is no evidence of any significant difference in the geographic distribution of the expanded populations at either the regional or municipal level.

In terms of the remaining person attributes shown in Table 1.4(b) the most significant differences are:

- $38,000(2 \%)$ reduction in the number of people reported as not employed
- $38,000(9 \%)$ increase in the number of people reported as employed part time
- $35,000(1 \%)$ increase in the number of people reported as licensed to drive with a corresponding $2 \%$ reduction in the number of people reported as not licensed to drive.
- $21,000(15 \%)$ increase in the number of people reported as part time students with a corresponding $24,000(1 \%)$ reduction in the number of people reported as not being students.

These differences may reflect biases in the attributes of survey respondents relative to non respondents the reasons for which are not readily apparent. It could also be that the data pertaining to these attributes is more accurate for respondents than for non respondents. No attempt has been made to correct for these differences between the two databases. The differences are not expected to result in any major change in discretionary trip rates and distribution of characteristics.

### 1.5 Comparison of Adjusted Trip Totals

Table 1.5 compares the results of applying the factors recommended by Badoe (refer to Section 1.1) with the results obtained by expanding the respondent data to represent the total survey population.

The most significant absolute adjustments occur in the number of auto driver trips and are very similar in magnitude by both methods. The two methods produce adjusted trip totals that match within $7 \%$ in each of the 10 largest categories. The overall auto driver trip total matches within $1 \%$ for the categories for which adjustments were recommended by Badoe. The magnitude of the adjustments produced by expansion of the respondent database are more uniform, ranging in magnitude from $22 \%$ to $49 \%$, compared with $11 \%$ to $65 \%$ from the application of the adjustment factors to non respondent trips. The greater variation resulting from the factors applied to non respondent trips may be the result of differences in the respondent and non respondent population characteristics that are not adequately reflected in the stratification of trip and person characteristics. Expanding the respondent database to represent the total population results in an increase in long (over 25 km ) auto driver trips whereas no adjustments were recommended by Badoe for this category. Although the number of trips involved is small, the effect on traffic assignment will be proportionately much more significant because of the length of the trips involved.

The same general observations apply to local transit trips. The differences between the two methods are proportionately greater than for auto drivers but involve much smaller trip totals. Expansion of the respondent database results in a $34 \%$ increase in the number of discretionary trips made by local transit compared to a $13 \%$ obtained by applying the adjustment factors to non respondent trips. The larger increase in the respondent database is mostly attributable to higher trip rates for medium and long trips.

In the one category (short HBD with no driver's license) of auto passenger trip, for which a non respondent adjustment factor was recommended, the expansion of the respondent database resulted in a $4 \%$ higher trip total. No adjustment factor was recommended for licensed trip makers because the non respondent trip rate was higher than the respondent trip rate. Expansion of the respondent database resulted in a $16 \%$ reduction in the number of trips in that category and a $3 \%$ reduction in other categories for which no adjustments were recommended. The higher reported trip rates for non respondents than respondents could result from differences in the demographic characteristics of the two groups not being adequately reflected in the stratification. It could also reflect difference in travel behaviour directly related to respondent status (e.g.: who is most likely to be home to answer the survey). It is highly unlikely that non respondent auto passenger trips would be over reported. The differences are small in the context of the total number of trips.

### 2.0 Comparison of Respondent and Original TTS Trip Data

Tables 2.0(a) and (b) show the difference in expanded discretionary trip totals between the adjusted respondent database and the original TTS database. Table 2.0(a) provides comparisons stratified by selected person and household attributes. Table $2.0(\mathrm{~b})$ provides similar comparisons by trip attribute. In total the expanded number of discretionary trips is $24 \%$ higher in the respondent database.

### 2.1 Household Size

Significant differences in the percentage increase in discretionary trip totals exist between single person households, 2-person households and households of 3 or more persons (refer to Table 2.0(b)). This variation was to be expected, given the nature of the under reporting, and is consistent with Hassounah and Cheah's findings with respect to the 1986 TTS. The variations are relatively minor for households of more than 3 persons. The $1 \%$ increase for 1-person households results from the exclusion of household members under the age of 16 in the stratification used for expansion. There are a few isolated incidences of 2-person households with a respondent under the age of 16 .

### 2.2 Age

The greatest increase in the number of reported discretionary trips is in the 18 to 24 age range as would be expected given the high proportion of survey non respondents in that age range. There is no change in the refused age category or in the 11 to 17 age range because the data has not been modified. The increase in the number of trips becomes progressively smaller above age 60 because of the high proportion of respondents in the original database and the data from larger households were not modified.

### 2.3 Gender

The slightly larger increase in the proportion of trips made by males is consistent with the higher proportion of male non respondents than female.

### 2.4 Employment and Student Status

The above average increase in the number of discretionary trips made by part time students and employed persons reflects the unexplained differences between the expanded respondent and TTS populations. It could be an indication of a hidden bias in the adjustment procedure.

### 2.5 Geographic Distribution of Trips by Household Location

The non respondent correction produces a larger proportional increase in the number of discretionary trips made by households in Peel and York than in the other regions. Peel and York have the largest average household size and therefore the largest percentage of non respondents. At the municipal level the largest variation in the percentage increase is in the rural municipalities, ranging from a low of $13 \%$ for Uxbridge to a high of $33 \%$ for Whitchurch-Stouffville. The urban municipalities have increases ranging from $18 \%$ to $31 \%$ without any obvious pattern to the variations.

### 2.6 Driver's License Status

The data on driver's license status is included in Table 2.0(b). The below average ( $12 \%$ ) increase in the number of discretionary trips made by people without driver's licenses reflects two factors: a) under reporting of auto driver trips is much more significant than of auto passenger trips (see Section 2.7), and b) the apparent under representation of non drivers in the respondent database.

Table 2.0(a) - Discretionary Trip Totals by Person Attribute

# Table 2.0(b) - Discretionary Trip Totals by Trip Attribute 

### 2.7 Primary Mode

The increase in the auto driver mode ( $32 \%$ ) accounts for $90 \%$ of the total increase in discretionary trips. Local transit shows a similar percentage increase (34\%) but for a much smaller trip total. The expanded auto passenger discretionary trip total in the respondent database is lower than in the original TTS database. The difference can be attributed, in part, to the under representation of non drivers in the respondent database. Previous studies, including Badoe, showed no evidence of any under reporting of auto passenger
trips. An explanation could be that since auto passenger trips require co-ordination with another person (the driver) they are more likely to be accurately reported by a third party person than are trips made alone. The absolute changes in the magnitude of the trip totals for other modes, including GO Rail, are not very significant.

### 2.8 Trip Purpose

The largest absolute increase $(507,000)$ is in the number of home-based other trips. The largest relative increase ( $33 \%$ ) is in the number of non home-based trips. The tabulation by destination purpose shows a $47 \%$ increase in the number of second work trips many of which are likely to be non home-based trips made at lunch time. The fact that non home-based trips have the highest level of under reporting is consistent with those trips being the ones of which a third-party respondent is least likely to have knowledge. The number of first trips to work from non home locations shows the smallest increase ( $16 \%$ ).

### 2.9 Trip Origin Location

The percentage increase in trips by municipality of trip origin is similar in magnitude and distribution to the increases by municipality of residence.

### 2.10 Trip Start Time

Table 2.10 gives a comparison of discretionary trip totals by time of day. The differences between the respondent and TTS databases are shown as percentages of both the discretionary trip totals and the overall totals including home-based work and school trips. Figure 2.10 shows the difference in trip totals for a continuously moving 1 -hour time window.

The most significant increase, in both absolute and percentage terms, occurs in the middle of the day, as would be expected with the identified nature of the under reporting. The difference in the total number of trips reported prior to $9 \mathrm{a} . \mathrm{m}$. is relatively small suggesting that a person's first trip of the day is the most likely to be accurately reported by a third party. The correction for the p.m. peak period (3:30 to $6: 30)$ is more than twice as significant than the a.m. peak period, $11 \%$ compared to $5 \%$ of total trips.

## Table 2.10 - Discretionary Trips by Trip Start Time

| Start time | TTS <br> database | Respondent <br> database | Difference |  | Work \& School <br> Trips | Total <br> Difference |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| $4: 00-5: 59$ | 13,351 | 17,458 | 4,107 | $31 \%$ | 96,298 | $4 \%$ |
| $6: 00-8: 59$ | 530,778 | 636,254 | 105,476 | $20 \%$ | $1,800,072$ | $5 \%$ |
| $9: 00-15: 29$ | $1,969,569$ | $2,516,724$ | 547,155 | $28 \%$ | 865,691 | $19 \%$ |
| 15:30-18:29 | $1,281,545$ | $1,574,556$ | 293,011 | $23 \%$ | $1,403,765$ | $11 \%$ |
| 18:30-20:59 | 965,659 | $1,153,477$ | 187,818 | $19 \%$ | 275,259 | $15 \%$ |
| $21: 00-27: 59$ | 614,617 | 744,719 | 130,102 | $21 \%$ | 288,843 | $14 \%$ |
| Total | $5,375,519$ | $6,643,188$ | $1,267,669$ | $24 \%$ | $4,729,929$ | $13 \%$ |

### 2.11 Auto Trip Length

Figure 2.11(a) compares the auto driver discretionary trip length distributions from the TTS and respondent databases. Contrary to expectations there is little variation in the magnitude of the difference. It was expected that there would be a larger difference for short trips than for long trips. The median auto driver discretionary trip length in the respondent database is 5.6 km compared to 5.9 km in the original TTS database. The adjustment to short trips (under 5 km ) dominates the change in the total number of daily trips, accounting for almost $60 \%$ of the total increase, but it is the adjustment to the longer trips that has the greatest impact on traffic flows. Figure 2.11(b) shows that half of the increase in auto trip km comes from the increase in trips over 17 km in length.

### 2.12 Cordon Counts

Tables 2.12(a), (b) and (c) give comparisons between Cordon Counts and assigned traffic volumes for selected screen lines in the four regions (Toronto, Peel, York and Durham) for which cordon count information was collected in 1995 or 1996. Figures 2.12 (a) through (d) provide a summary by region referenced to the mean hourly count for that region. The comparisons were obtained by performing EMME/2 assignments of auto driver trip matrices extracted from the TTS and respondent databases. A number of problems have to be recognized when making comparisons between TTS and cordon count data:

1. Difference in timing. The Cordon Count Data were collected in the early summer of 1995 (1996 in Durham), the TTS in the fall of 1996. Natural growth, economic recovery and seasonal variations are all factors that would likely contribute to higher traffic volumes at the time of the TTS relative to the cordon counts.
2. The TTS data represents a 3-month average. The cordon counts consist mostly of one day counts at each location. Substantial day to day variations in traffic volumes are possible.
3. Vehicle classification. The comparison is between auto drivers, taken from the TTS database and private vehicles taken from the cordon counts. The TTS database does not identify the type of vehicle. It is often difficult for the cordon count survey crews to distinguish between private and light commercial vehicles. Many pickup trucks, small vans and SUV's could belong to either category.
4. Time distribution. The cordon count data is based on the times at which vehicles are observed on the street whereas the TTS data consists of reported trip start times. The cordon count information is collected in 15 minute time intervals. The TTS database contains the exact time that each trip is reported as starting but most survey respondents give approximate times - usually to the nearest 10,15 or 30 minutes. As a result, the TTS database contains sharp peaks that generally coincide with the dividing lines between count periods. With the exception of the evening and 15 -hour counts for Toronto, the count data has been extracted for time periods that are 15 minutes later than trip start time ranges used for the TTS data. The Toronto cordon count program did not collect data after 9 p.m., hence the need to use the same time intervals as for the TTS in order to cover the same length of time. Shifting the cordon count time period by 15 minutes produces counts that are slightly higher in the a.m. peak but has negligible impact on the counts for the other time periods.

Table 2.12(a) - Peak Period Cordon Count Comparisons

|  | Morning Peak (6:00-8:59) |  |  |  |  | Evening Peak (3:30-6:29) |  |  |  |  |

Figure 2.12(a) - Cordon Count Summary - Toronto

Figure 2.12(b) - Cordon Count Summary - Peel Region

Figure 2.12(c) - Cordon Count Summary - York Region

Figure 2.12(d) - Cordon Count Summary - Durham Region

5. Trip length. The TTS should, in theory, contain a representative sample of all trip lengths whereas it is the vehicles making long trips that are most likely to be counted in the cordon count program. The difference is significant. A select link EMME/2 assignment of total daily auto driver trips produced a median trip length of 21.2 km for trips crossing the Toronto boundary compared to a median length of 5.4 km for all trips.
6. Network simulation. The aggregation of TTS data to screenlines relies on a network simulation of the routes taken between origin and destination. The accuracy with which the routes correspond with actual routings depends on how well the network is represented. The location of centroid connectors, particularly in locations where the screen line does not follow a natural barrier such as a river or railway line, is of particular importance.

The above concerns make it difficult to draw definitive conclusions from comparisons made between cordon counts and TTS data.

The 15 -hour assigned volumes from the respondent database give a reasonably close match to the observed counts in both Toronto and Peel when combined across all screen lines ( $95 \%$ for Toronto and $98 \%$ for Peel). The volumes are significantly closer than those obtained from the original TTS database ( $83 \%$ and $84 \%$ ). Given the difference in timing, the under representation of actual traffic volumes is likely to be greater but it may be concluded that the respondent database gives volumes that are more accurate than the original TTS database. Compared to the cordon counts both the original TTS and the respondent databases would appear to over represent the a.m. and p.m. periods relative to off peak travel. It is unlikely that the TTS would over-represent trips, for either respondents or non respondents, or that any hidden bias, related to the selection of respondents, would create differences of this magnitude. It is more likely the assignment procedures and the definition of compatible time intervals that are the problem.

For York Region the 12.5 -hour screenline volumes from the respondent database were, on average, $12 \%$ higher than the count whereas the TTS data gave volumes $6 \%$ lower than the counts. The differences, relative to Toronto and Peel, are consistent with the exclusion of evening travel from the comparison and more pronounced peaks associated with the high proportion of commuter travel to and from Toronto.

Durham is the only region that has cordon count data for 1996, the same year as the survey, but shows the greatest discrepancies between the cordon count and survey data. The original TTS data produced volumes averaging $73 \%$ of the counts and the respondent database $84 \%$. Much of the under representation is of volumes crossing Highway 401 suggesting that there might be a problem specific to that screenline, possibly in the way it is represented in the assignment relative to real life.

When the results from the four regions are taken together it would appear that the correction for the under reporting of non respondent trips account for $65 \%$ of the apparent under reporting of total daily traffic. The level of under reporting that remains is hard to assess because of the previously mentioned limitations in making comparisons with the cordon counts. There is also no valid basis on which to base any further adjustment of the data. The correction for under reporting has a greater impact in the p.m. peak than in the a.m. peak providing a more realistic representation of the relative magnitudes of the two peak periods. Over representation of the peak period travel, relative to off-peak, appears to be a problem and is addressed in more detail in Chapter 5.

### 2.13 Transit Ridership Counts

Table 2.13 compares the number of transit boardings recorded in the TTS and respondent databases with the transit ridership counts used in the original validation of the 1996 TTS data.

The under reporting adjustment increased the discretionary trip boardings for TTC buses by $38 \%$ producing an almost exact match with the ridership counts obtained from the TTC. Streetcar ridership is still significantly under represented but by a smaller amount than in the original TTS database ( $25 \%$ vs. $33 \%$ ). The 1996 TTS did not collect information on transfers between subway lines or between the subway and the Scarborough RT. In order to obtain a comparable number, the TTC boarding counts were adjusted using information from the 1986 TTS. The subway and SRT count numbers are therefore less reliable than for bus and streetcar. There is no obvious explanation as to why the TTS would over represent subway
ridership in either the TTS or respondent databases. It should be noted that the TTC ridership counts were taken at a different time on each route over a two year period.

Discretionary trips are not a significant factor in either GO Rail or GO Bus Ridership. The adjustment for under reporting therefore has little effect on total ridership, which closely matches the observed ridership counts in both the TTS and respondent databases.

The respondent database also gives total ridership figures that are very close to the observed daily ridership counts for Mississauga Transit. In the other municipalities for which counts were available at the time of the validation, the reported ridership in the TTS was significantly higher ( $20 \%$ to $59 \%$ ) than the counts. The correction for under reporting increases those differences. However both the ridership totals and the differences are small in absolute terms.

The TTS validation included comparisons between TTS and annual ridership data for the Hamilton Street Railway, which suggested that bus ridership in the City of Hamilton was under reported by $10 \%$ to $15 \%$. The respondent database would correct for that difference.

Table 2.13 - Daily Transit Boardings

| Operator | Discretionary |  |  | Work \& School | Total Change | Count | Difference |  |

*Excludes transfers between lines.

### 3.0 Global Adjustment Factors

A primary reason for expanding the respondent database to represent the total survey population was to avoid the distortion of trip characteristics that might be introduced by applying constant adjustment factors to trip categories that might contain a variation in the level of under reporting. The concern related primarily to trip start time and trip length. The comparisons between the expanded respondent data and the original TTS data showed no evidence of any significant variation in the implied level of under reporting associated with trip length (Figure 2.11(a)). The implied level of under reporting was almost constant between $9 \mathrm{a} . \mathrm{m}$. and $9 \mathrm{p} . \mathrm{m}$. (Figure 2.10). Of the total daily discretionary trips, $79 \%$ are made between 9 a.m. and 9 p.m. Under reporting of discretionary trips that start before $7: 30 \mathrm{a} . \mathrm{m}$. or after $10 \mathrm{p} . \mathrm{m}$. would appear to be minimal but the number of trips affected is very small.

Household size is the most significant demographic factor affecting the magnitude of under reporting but household size has not been identified as a major factor with respect to other trip characteristics nor are variations in household size distribution likely to have a significant effect on the overall level of under reporting. Other demographic factors, primarily gender, age, and possession of a driver's license, would appear to correlate more with overall trip rates and the probability of a person being a respondent than they do with levels of under reporting for non respondent. The analysis also produced little evidence of geographic variations in levels of under reporting.

The two most significant factors affecting the levels of under reporting are trip purpose and mode of transport. Global under reporting correction factors based on these two attributes may well produce trip rates and trip distributions that are as reliable and robust as any other method of adjusting the TTS data. Table 3.0 provides a summary of the differences in expanded discretionary trip totals between the respondent and TTS trip databases. The data are sorted in order of the relative magnitude of the daily trip totals. The comparison is restricted to persons in the age range 18 to 62 . No adjustments, or only partial adjustments, were made in other age categories due to insufficient data for respondents.

The figures shown in bold type, for auto drivers and local transit trips, are recommended as correction factors that can be applied to any subset of the 1996 TTS data extracted using those trip attributes. The significance of non respondent under reporting of discretionary trips is greatest with respect to auto driver trips largely because they account for $64 \%$ of total daily auto trips. The relative magnitude of the under reporting of discretionary trips made by local transit is similar to auto drivers ( $34 \%$ vs. $33 \%$ ). The difference is less significant, however, because discretionary trips only account for $34 \%$ of total daily transit trips. Transit planning generally focuses on peak period demand where discretionary travel is even less of a factor.

Adjustments to other modes are not recommended for the following reasons:
a) Auto passengers are the second most significant mode in terms of total daily discretionary travel but there is no evidence of under reporting. The fact that the trip rates for non respondents is higher than for respondents in many sub categories is most likely due to unidentified biases in the two populations.
b) Information on discretionary walk trips should only have been collected for connecting links between trips made by other modes. Discretionary walk trip information in the TTS database is meaningless for most purposes and should not be used.
c) The total numbers of trips made by taxi and bicycle are small and of minor importance to most transportation planning issues. The adjustment factors are consistent with those for auto drivers and local transit and could be used if there is a need. It is interesting to note that $75 \%$ of the adjusted daily taxi trip total consists of discretionary trips.
d) The number of discretionary trips made on the other modes, including GO Train, is too small for the adjustment factors to have any statistical reliability or significance.

The global adjustment factors should not be applied to subsets of the TTS data that are heavily biased in their selection criteria in respect to the relative proportions of respondents and non respondents (e.g.- trip makers under the age of 18). Similarly, it would be inappropriate to apply the factors to trip selections that include a high proportion of trips made between $10 \mathrm{p} . \mathrm{m}$. and 8 a.m.

Table 3.0 - Global Trip Adjustment Factors

| Primary Mode | Ratio of Adjusted to Original Trip Totals |  |  |  | Total Discretionary trips after adjustment | Proportion of total daily trips (incl. Work \& school) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Unknown | 1.28 | 0.77 | 1.17 | 0.98 | 712 | 49\% |
| Total | 1.27 | 1.22 | 1.37 | 1.28 | 5,419,980 | 59\% |

### 4.0 Analysis of Discretionary Travel

The following analysis has been performed using the respondent data expanded to match the demographic characteristics of the TTS population terms of the distribution of age, gender, household size and driver's license status for women. The analysis is based on residents of the GTA and Hamilton-Wentworth. Sections 4.1 through 4.7 deal with the characteristics of discretionary trips and Sections 4.8 through 4.10 with the characteristics of the trip makers. Section 4.11 provides a summary. For the purpose of this analysis, discretionary travel has been divided into three sub-categories:

- Home-based shopping - trips with one end (origin or destination) at home and the other at a location where the destination purpose of the current, or the previous trip, was given as shopping.
- Home-based other - trips with one end at home and the other at a location where the purpose was given as something other than work, school or shopping.
- Non home-based - all trips where neither the origin nor the destination is given as home.

The above trip purposes, together with home-based work and home-based school, define the total travel market covered by the TTS survey. While the focus of this analysis is on discretionary travel some comparisons with home-based work and school trips are included for the purpose of highlighting the differences.

### 4.1 Total Travel

Figures 4.1(a), (b), (c) and (d) show the relative significance of the 5 trip purposes for the four main modes of travel. The Figures show the relative magnitude both in terms of the number of daily trips made and the total distance travelled measured in a straight line from origin to destination.

Figure 4.1(a) - Auto Driver Trip Purpose Distribution

Total discretionary travel accounts for $67 \%$ of total daily auto driver trips and $53 \%$ of total daily auto travel distance. Home-based shopping is the least significant of the three discretionary trip purposes accounting for $13 \%$ of daily trips but only $5 \%$ of daily travel distance for the auto driver mode.

Figure 4.1(b) - Auto Passenger Trip Purpose Distribution

Discretionary travel accounts for about the same proportion of daily auto passenger trips ( $65 \%$ ) as for auto drivers and a higher proportion of total daily passenger travel distance ( $67 \%$ ).

Figure 4.1(c) - Local Transit Trip Purpose Distribution

Discretionary travel is less significant for local transit use than it is for either auto drivers or auto passengers. In total, discretionary travel accounts for $37 \%$ of the total daily trips made by local transit and $31 \%$ of the passenger travel distance.

The amount of discretionary travel reported on GO Rail, at $12 \%$ of trips and $10 \%$ of travel distance, is significantly higher than the $3 \%$ reported in the 1995 GO Rail survey. The GO Rail survey, however, had a $31 \%$ non response rate for that question. Differences in methodology, sampling and response rates make it difficult to draw conclusions as to the relative reliability of the two surveys. The one conclusion that can
be drawn is that discretionary travel is of relatively minor importance to GO Rail operations. The remainder of this analysis is restricted to the automobile and local transit modes.

Figure 4.1(d) - GO Rail Trip Purpose Distribution

Home-based other is the most significant of the three discretionary trip purposes accounting for $33 \%$ of total daily auto driver trips, $36 \%$ of auto passenger trips and $18 \%$ of daily local transit trips. Non homebased is the second most important discretionary purpose accounting for $21 \%$ of auto driver trips, $13 \%$ of auto passenger trips and $10 \%$ of local transit use. Table 4.1 gives a further breakdown of non home-based trips by origin and destination purposes. It shows that $50 \%$ of non home-based trips have a place of work as either their origin or destination. Seventeen percent are totally work related (work to work), $13 \%$ are to work from other origins and $20 \%$ from work to other destinations.

Table 4.1 - Origin \& Destination Purpose of Total Daily Non Home-based Trips All Modes

| Origin | Destination Purpose |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Purpose | Other | Work | School | Shopping | Total |
| Other | 484564 | 216766 | 27402 | 154188 | 882920 |
| Work | 285117 | 342048 | 10202 | 108538 | 745905 |
| School | 50485 | 15043 | 5859 | 11276 | 82663 |
| Shopping | 114677 | 27484 | 2924 | 145176 | 290262 |
| Total | 934843 | 601341 | 46387 | 419178 | 2001749 |

| Origin | Destination Purpose |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Purpose | Other | Work | School | Shopping | Total |
| Other | $24 \%$ | $11 \%$ | $1 \%$ | $8 \%$ | $44 \%$ |
| Work | $14 \%$ | $17 \%$ | $1 \%$ | $5 \%$ | $37 \%$ |
| School | $3 \%$ | $1 \%$ | $0 \%$ | $1 \%$ | $4 \%$ |
| Shopping | $6 \%$ | $1 \%$ | $0 \%$ | $7 \%$ | $15 \%$ |
| Total | $47 \%$ | $30 \%$ | $2 \%$ | $21 \%$ | $100 \%$ |

Home-based shopping is the least significant of the three trip purposes accounting for $13 \%$ of auto driver trips, $16 \%$ of auto passengers and $9 \%$ of local transit trips. The proportion of total daily travel distance is significantly lower, at $5 \%, 9 \%$ and $6 \%$ respectively.

### 4.2 Mode Splits

Figures 4.2(a) and (b) compare the local transit and auto passenger mode splits for the three discretionary trip purposes with those for home-based work trips. Transit mode splits for discretionary travel are about one half of what they are for work trips. The auto passenger mode shares are higher than for work trips. Outside Toronto and Hamilton the local transit mode shares for discretionary travel are in the 0 to $3 \%$ range. Auto passenger mode shares are lower for non home-based trips ( $11 \%$ ) then for home-based shopping ( $18 \%$ ) or home-based other ( $17 \%$ ). Auto passenger mode shares are higher in HamiltonWentworth than in the other regions including Toronto. It should be remembered, however, that the TTS did not collect data on walk trips other than to work and school. Walk and cycle trips for all trip purposes have been excluded for the purpose of this comparison.

Figure 4.2(a) - Local Transit Mode Shares

Figure 4.2(b) - Auto Passenger Mode Shares

### 4.3 Trip Length

Figure 4.3 gives a comparison of median trip lengths for each combination of mode and trip purpose. Trip length is measured in a straight line and therefore likely under represents median road travel distances by $15 \%$ to $20 \%$ on a consistent basis. Discretionary trips are generally much shorter than work related trips. The trip category with the shortest median trip length is auto driver home-based shopping. At 2.4 km , the median is less than one quarter of that for auto driver work trips. The short length of shopping trips explains the differences in the proportion of travel distance relative to number of trips in the previous section. The median trip length is longer for auto passengers than it is for either auto drivers or local transit in all but the school trip purpose category. For shopping trips it is more than three times the median for auto driver trips. This difference in median trip length implies that short distance local trips are the most likely to be made by a lone driver without passengers. The exception is serve-passenger trips where the median trip length is 3.2 km .

Figure 4.3 - Median Trip Length (km)

### 4.4 Auto occupancy

It is not possible to obtain reliable estimates of auto occupancy from the TTS data because there is no information on who rides with whom and no trip information for children under age 11 - the most likely people to be auto passengers. Comparisons by trip purpose are further complicated by the fact that drivers and passengers do not necessarily share the same trip purpose. The fact that home-based shopping trips have the highest proportion of auto passengers suggests that auto occupancy is likely to be higher on shopping trips than for other trip purposes. Dividing the combined total of auto passenger and auto driver trips by the number of auto driver trips gives a reference number that can be used for comparison between trip purposes. Weighting the values by average trip length gives an average travel value that should be more representative of the value one would expect to observe on the street. Table 4.4 shows both the trip and travel values calculated in this manner. The values for discretionary trips, particularly shopping, are significantly higher than for home-based work trips. The mean travel value is the one that should be compared with on street observations such as the cordon counts. Observed auto occupancies from the cordon count program range from 1.15 to 1.4 depending on the location of the screenline and the time of day.

Table 4.4 - Mean Auto Occupancy Indicators by Trip Purpose

|  | Trip | Travel |
| :--- | ---: | ---: |
| Home-based Shopping | 1.25 | 1.8 |
| Non Home-based | 1.14 | 1.25 |
| Home-based Other | 1.22 | 1.6 |
| Home-based Work | 1.14 | 1.18 |

### 4.5 Start Time

Figure 4.5 (a) shows the distribution of discretionary trip start times for the three main modes of travel. The peak hour for auto driver trips is between 3 and $4 \mathrm{p} . \mathrm{m}$. although there is little change in hourly volume until 7:30 p.m. There is a less significant peak in the morning between 8 and $9 \mathrm{a} . \mathrm{m}$. Discretionary auto passenger trips occur mostly in the evening, between 5 and 10 p.m. The number of discretionary trips made by local transit peaks between 3 and 5:30 p.m.

Figure 4.5(a) - Discretionary Travel Trip Start Times by Mode of Travel

Figure 4.5(b) shows the distribution of start times for auto driver trips broken down by trip purpose. There is a pronounced peak in both home-based other and non home-based trips prior to $9 \mathrm{a} . \mathrm{m}$. Much of that peak can be attributed to serve-passenger trips or detours. Figures 4.5(c) and (d) show the trip start time distributions for serve-passenger origins and destinations. The figures show that of the 130,000 auto driver trips made to a serve-passenger destination during the a.m. peak hour approximately 50,000 of the drivers then return home and 48,000 continue on to work. In total, the serve-passenger component accounts for $76 \%$ of the home-based other auto driver trips in the a.m. peak hour and $52 \%$ in the p.m. peak hour. Trips between a serve-passenger origin and a work destination account for $39 \%$ of the non home-based auto driver trips that start in the a.m. peak hour.

Figure 4.5(b) - Auto Driver Start Times by Trip Purpose

Figure 4.5(c) - Trip Start Times for Serve-passenger Origins

Figure 4.5(d) - Trip Start Times for Serve-passenger Destinations

The TTS does not provide any data as to who the passengers are on serve-passenger trips or their trip purposes. Since the vast majority of serve-passenger trips occur in the peak periods it would seem highly likely that they are either work or school trips. It could be argued that a serve-passenger trip to take someone else to work or school is not discretionary travel. Without those trips there would be no a.m. peak for auto driver discretionary trips. Removing the serve-passenger component would have a much smaller effect in the p.m. peak and virtually none at all in the off peak.

Figures 4.5 (e) and (f) show the distribution of trip start times for auto passenger and local transit trips. The most significant component of auto passenger discretionary travel consists of home-based other trips made between $4: 30$ and 11 p.m. Home-based other trips made on local transit have a significant peak between 3 and 6 p.m. Home-based shopping and non home-based trips are more uniformly distributed throughout the day with the majority of auto passenger trips being made between 10 a.m. and 9 p.m. and local transit trips between 9 a.m. and 8 p.m.

Figure 4.5(e) - Start Times for Auto Passenger Trips

Figure 4.5(f) - Start Times for Local Transit Trips

### 4.6 Destinations

In the following discussion the new City of Toronto has been divided into 5 aggregations of the old planning districts. These areas are treated as equivalent to municipalities in the other regions for the purpose of analyzing travel patterns. Table 4.6 (a) shows that $74 \%$ of shopping trips are made to locations within the municipality of residence and $92 \%$ within the same region. The downtown of Toronto (PD 1) is not a significant attraction for shopping trips but $25 \%$ of the shopping trips from Vaughan and $20 \%$ from Markham are made to Toronto.

## Table 4.6(a) - Home-based Destinations by Municipality of Residence

| Residence/ Origin | Home-based Shopping |  |  |  |  |  | Home-based Other |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
| PD 1 | 62\% | 98\% | 62\% | 98\% | 2\% | 1\% | 53\% | 93\% | 53\% | 93\% | 6\% | 1\% |
| PD2-6 | 64\% | 98\% | 13\% | 98\% | 2\% | 0\% | 55\% | 93\% | 20\% | 93\% | 6\% | 1\% |
| PD7-9 | 77\% | 91\% | 4\% | 91\% | 9\% | 0\% | 59\% | 86\% | 7\% | 86\% | 13\% | 1\% |
| PD10-12 | 60\% | 88\% | 4\% | 88\% | 12\% | 0\% | 48\% | 84\% | 7\% | 84\% | 15\% | 1\% |
| PD13-16 | 80\% | 93\% | 3\% | 93\% | 7\% | 0\% | 65\% | 89\% | 7\% | 89\% | 11\% | 1\% |
| Brock | 49\% | 74\% | 0\% | 0\% | 12\% | 15\% | 56\% | 69\% | 0\% | 3\% | 10\% | 17\% |

| Whitby | 67\% | 99\% | 0\% | 1\% | 0\% | 0\% | 60\% | 90\% | 2\% | 6\% | 3\% | 1\% |
| Oshawa | 86\% | 98\% | 0\% | 1\% | 1\% | 0\% | 76\% | 93\% | 1\% | 3\% | 2\% | 2\% |
| Clarington | 48\% | 98\% | 0\% | 2\% | 0\% | 0\% | 54\% | 89\% | 1\% | 5\% | 2\% | 3\% |
| Georgina | 66\% | 94\% | 1\% | 3\% | 2\% | 1\% | 60\% | 87\% | 0\% | 4\% | 5\% | 4\% |
| East Gwillimbury | 11\% | 93\% | 1\% | 5\% | 0\% | 2\% | 31\% | 82\% | 4\% | 9\% | 4\% | 5\% |
| Newmarket | 91\% | 97\% | 1\% | 1\% | 0\% | 1\% | 73\% | 88\% | 2\% | 7\% | 1\% | 4\% |
| Aurora | 54\% | 95\% | 2\% | 4\% | 0\% | 1\% | 56\% | 86\% | 3\% | 10\% | 2\% | 2\% |
| Richmond Hill | 70\% | 92\% | 0\% | 8\% | 0\% | 0\% | 53\% | 79\% | 3\% | 19\% | 2\% | 1\% |
| Whit.-Stouff. | 45\% | 96\% | 0\% | 2\% | 2\% | 0\% | 45\% | 81\% | 3\% | 11\% | 6\% | 1\% |
| Markham | 67\% | 79\% | 2\% | 20\% | 1\% | 1\% | 56\% | 67\% | 4\% | 29\% | 2\% | 1\% |
| King | 35\% | 79\% | 3\% | 7\% | 3\% | 11\% | 31\% | 58\% | 5\% | 26\% | 7\% | 9\% |
| Vaughan | 61\% | 73\% | 1\% | 25\% | 2\% | 0\% | 49\% | 61\% | 4\% | 35\% | 3\% | 1\% |
| Caledon | 53\% | 80\% | 0\% | 3\% | 8\% | 10\% | 44\% | 68\% | 2\% | 13\% | 8\% | 10\% |
| Brampton | 92\% | 97\% | 0\% | 2\% | 0\% | 0\% | 76\% | 87\% | 2\% | 8\% | 3\% | 1\% |
| Mississauga | 87\% | 89\% | 1\% | 8\% | 3\% | 0\% | 73\% | 76\% | 4\% | 18\% | 5\% | 1\% |
| Halton Hills | 92\% | 92\% | 0\% | 1\% | 6\% | 1\% | 67\% | 75\% | 1\% | 4\% | 17\% | 4\% |
| Milton | 68\% | 81\% | 0\% | 2\% | 16\% | 1\% | 68\% | 80\% | 1\% | 5\% | 10\% | 5\% |
| Oakville | 80\% | 85\% | 1\% | 3\% | 12\% | 0\% | 77\% | 82\% | 2\% | 6\% | 9\% | 2\% |
| Burlington | 92\% | 95\% | 0\% | 0\% | 4\% | 0\% | 72\% | 80\% | 1\% | 3\% | 15\% | 2\% |
| Flamborough | 29\% | 54\% | 0\% | 0\% | 32\% | 14\% | 37\% | 68\% | 0\% | 0\% | 21\% | 11\% |
| Dundas | 43\% | 89\% | 0\% | 0\% | 11\% | 0\% | 38\% | 88\% | 0\% | 0\% | 9\% | 3\% |
| Ancaster | 50\% | 97\% | 0\% | 0\% | 1\% | 2\% | 40\% | 89\% | 0\% | 1\% | 5\% | 5\% |
| Glanbrook | 6\% | 96\% | 0\% | 0\% | 4\% | 0\% | 22\% | 87\% | 0\% | 5\% | 4\% | 5\% |
| Stoney Creek | 36\% | 93\% | 0\% | 0\% | 3\% | 4\% | 45\% | 88\% | 0\% | 1\% | 7\% | 4\% |
| Hamilton | 89\% | 95\% | 1\% | 1\% | 4\% | 1\% | 81\% | 90\% | 0\% | 1\% | 5\% | 3\% |
| Total | 74\% | 92\% | 4\% | 43\% | 5\% | 1\% | 62\% | 85\% | 8\% | 45\% | 7\% | 2\% |

There is less regional self-containment of home-based other trips with $62 \%$ of destinations within the same municipality and $85 \%$ within the same region. The most significant cross-boundary movements are again from Vaughan to Toronto (35\% of the Vaughan total) and Markham to Toronto ( $29 \%$ of the Markham total).

Non home-based trips, as one would expect, are more dispersed than are home-based trips. Table 4.6(b) shows the distribution of destinations by both municipality of residence and trip origin. By trip origin, 53\%
are self-contained within the same municipality and $79 \%$ within the same region. Downtown Toronto is more significant as a destination for non home-based trips than it is for home-based trips, accounting for $10 \%$ of the total from all areas. Vaughan and Markham again show the highest proportion of crossboundary trips into Toronto at $40 \%$ and $37 \%$ respectively.

Table 4.6(b) - Non Home-based Trip Destinations

| Residence/ Origin | By Place of Residence |  |  |  |  |  | By Trip Origin |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Hamilton | 76\% | 86\% | 1\% | 3\% | 8\% | 3\% | 77\% | 89\% | 1\% | 1\% | 6\% | 3\% |
| Total | 50\% | 77\% | 10\% | 49\% | 11\% | 2\% | 53\% | 79\% | 10\% | 48\% | 12\% | 2\% |

Table 4.6(c) shows the 12 traffic zones (1996 GTA zone system) that have the most non home destinations for each of the three trip purposes. It shows the extent to which shopping trips are concentrated at the major shopping centres with the top 12 traffic zones accounting for almost $20 \%$ of all shopping trips. In comparison, the top 12 zones account for less than $7 \%$ of home-based other trips and $4.4 \%$ of non homebased trips. Ten of the 12 top traffic zones are the same for both home-based shopping and home-based other trips. Pearson Airport stands out as the number one destination for non home-based trips accounting for $50 \%$ more destinations than any other zone.

Table 4.6(c) - Most Common Destinations by Traffic Zone
Home-based Shopping

| Rank | Zone | Location | Municipality | Trips | Cum. \% |
| ---: | ---: | :--- | :--- | ---: | ---: |
| 1 | 1579 | Square One | Mississauga | 14740 | $2.5 \%$ |
| 2 | 2586 | Limeridge Mall | Hamilton | 12662 | $4.6 \%$ |
| 3 | 425 | Scarborough Town Centre | Toronto | 12011 | $6.6 \%$ |
| 4 | 295 | Yorkdale | Toronto | 11055 | $8.4 \%$ |
| 5 | 654 | Oshawa Centre | Oshawa | 10038 | $10.1 \%$ |
| 6 | 3 | Sherway Gardens | Toronto | 9492 | $11.6 \%$ |
| 7 | 228 | Eaton Centre | Toronto | 9159 | $13.2 \%$ |
| 8 | 1657 | Bramalea City Centre | Brampton | 8429 | $14.6 \%$ |
| 9 | 535 | Pickering Town Centre | Pickering | 8260 | $15.9 \%$ |

### 4.7 Age and Gender

Figure 4.7(a) shows the total daily discretionary trip rate by age and gender of the trip maker. The combined trip rate, for men and women, remains relatively constant at about two trips per day between the ages of 35 and 70. Women make more trips than men below the age of 50 but the reverse is true above age 50.

Figure 4.7(a) - Daily Trip Rates by Gender and Age

Figure 4.7(b) shows the daily trip rates with a further break down by trip purpose. It shows that women make significantly more shopping trips than men do up to age 65 and that there is a noticeable increase in the rate for both genders between ages 60 and 65 . The greatest number of non home-based trips are made by people in the 30 to 50 age range. The home-based other trip rates are higher than for either of the other two trip purposes for all age ranges. The rate for women reaches a peak around age 40 at which point it is significantly higher than for men. The rate for men does not peak until after age 60 at which point men are making more trips than women

### 4.8 Employment Status

Figures 4.8(a), (b) and (c) give the mean daily trip rates for each of the three trip purposes by age category and employment status. Shopping trips are mostly made by people who are not employed with the average rate for all age groups being almost double that for people who are employed full time. People who work at home, either full time or part time, have the highest trip rate for both non home-based and home-based other trip purposes. People who are not employed make the fewest non home-based trips as would be expected given the high proportion ( $50 \%$ ) of non home-based trips that are related to place of employment (Table 4.1). Those employed full time outside the home make the fewest home-based other trips.

### 4.9 Driver's License Status

Figure 4.9 shows that both men and women who are licensed to drive make two to three times as many discretionary trips as do people of the same gender and age group who are not licensed to drive.

Figure 4.7(b) - Daily trip Rates by Age, Gender and Trip Purpose

Non home-based

Figure 4.8(a) - Home-based Shopping Trip Rates by Employment Status

Age Group
Figure 4.8(b) - Non Home-based Trip Rates by Employment Status

Age Group

Figure 4.8(c) - Home-based Other Trip Rates by Employment Status

Figure 4.9 - Discretionary Trip Rate by Gender \& License Status

### 4.10 Auto Availability

Figure 4.10 shows that, on average, persons living in households with one or more autos available report making two to three times as many discretionary trips as do people living in households with no vehicles available. The number of automobiles available does affect the trip rate but not nearly to the extent that the first automobile does.

Figure 4.10 - Discretionary Trip Rate By Region \& Auto Availability

### 4.11 Summary

Peak period travel consists primarily of home-based work and school trips but discretionary trips account for more than half of total daily travel by automobile. School trips are mostly made by people under the age of 25 and work trip rates diminish rapidly after age 55. In contrast the frequency of discretionary travel remains relatively constant from mid thirties into old age with little evidence of any significant reduction in trip making frequency until age 75 or 80 . The significance of discretionary travel is therefore certain to increase as baby boomers approach retirement age. Between 1986 and 1996 the median age of the population in the GTA increased by 2.6 years and the number of people over age 65 increased by $50 \%$ (1996 TTS Report 5).

Outside of Toronto and Hamilton, local transit does not currently play a significant role in serving discretionary travel. Local transit mode splits are in the 0 to $3 \%$ range. Even in Toronto and Hamilton the transit mode splits are one half, or less, what they are for work trips. The possession of a driver's license and auto availability are clearly the two factors that most determine the frequency of discretionary travel.

The following paragraphs provide a point by point summary of the travel characteristics of each of the three discretionary trip purposes.

## Home-based Shopping

- $13 \%$ of total daily auto driver trips but only $5 \%$ of total auto travel distance.
- Highest transit use of the three discretionary trip purposes ( $16 \%$ transit mode split in Toronto, 3\% in the rest of the GTA and 7\% in Hamilton-Wentworth).
- Trips are short (median trip length 2.7 km ).
- High proportion of auto passengers, particularly for longer trips (mean auto occupancy estimated at 1.8 persons).
- Trips are generally made between 9 a.m. and $7 \mathrm{p} . \mathrm{m}$. with no significant peak period.
- Highest trip rates are for persons over age 35 who are not employed.
- Significant concentrations of the non home end in the zones containing major shopping centres.
- Not a significant factor in over all network congestion.
- May be a source of local problems with respect to parking and ease of access onto the road network.

## Non Home-based

- $21 \%$ of total daily auto travel
- Least likely of all trip purposes to use local transit ( $13 \%$ transit mode split in Toronto, $2 \%$ in the rest of the GTA and $3 \%$ in Hamilton-Wentworth).
- Highest auto driver mode share $(81 \%)$ of any trip purpose.
- Trips are mostly made between $10 \mathrm{a} . \mathrm{m}$. and 6 p.m.
- Highest trip rates are for persons employed outside the home.
- Secondary peak, prior to 9 a.m., results from detours to serve auto passengers on the way to work.
- $50 \%$ of trips have one, or both, ends at a work location.

## Home-based Other

- $33 \%$ of total daily auto driver trips and $27 \%$ of total auto travel distance.
- Mode split characteristics fall midway between home-based shopping and non home-based trips.
- Majority of trips are made after 2 p.m. with the peak, for both auto drivers and passengers, occurring at around 7 p.m.
- A secondary peak, for auto drivers only, occurs before 9 a.m. consisting almost entirely of trips made to serve-passengers travelling to work and/or school.
- People who work at home have the highest daily trip rate, those working full time outside the home the lowest.

### 5.0 Modeling Issues

In recent years modeling efforts in the GTA, including both the full and simplified GTA models, have focused mainly on the a.m. peak period. Reasons for that include ease of simulation and the fact that the number of trips reported in the 1986 TTS was higher in the a.m. peak than in the p.m. peak, significantly so for public transit. Most travel in the a.m. peak consists of trips from home to work or school made on a regular daily basis. Future trip generation and attraction totals can be projected, with reasonable confidence, from estimates of population, employment and school enrolment. Travel behaviour relationships in the p.m. peak period, and in the off-peak, are more complex.

Figure 5.0(a) shows the reported start time distribution of auto trips in the 1996 TTS after adjustment for under reporting of non respondent trips. Figure $5.0(\mathrm{~b})$ shows the resulting start time distribution of travel distances measured in a straight line from origin to destination. Both Figures show the p.m. peak 1 hour for auto drivers to be $5 \%$ to $10 \%$ higher than the a.m. peak 1 hour. The p.m. peak also extends over a much longer period of time. Cordon and other on-street count information generally show larger differences ( $10 \%$ to $15 \%$ ) in the a.m. and p.m. peak period volumes. The TTS may also under state the difference between a.m. and p.m. peaks for reasons which are discussed in the following sections.

Figure 5.0(a) - Auto Driver \& Passenger Trip Start Time Distribution

Figure 5.0(b) - Auto Travel Start Time Distribution

Since the highest demands on the road network occur in the p.m. peak period it is necessary to have p.m. peak period simulation models to determine the peak demand. It is also necessary to simulate total daily and annual traffic for the economic justification of new facilities, the calculation of total consumption of non renewable fossil fuels and the analysis of air quality. The analysis in Chapter 4 showed that the majority of total daily automobile travel is not directly related to work or school and that the proportion of off-peak non work and non school travel is likely to increase in the future.

In addressing the need to simulate total daily travel one needs to be clear as to the limitations of the TTS data. Section 5.1 discusses some of these limitations. The remainder of this chapter is devoted to identification of specific modeling issues. While some potential solutions are suggested the actual testing of these ideas, and the associated model development, are beyond the scope of this project and report.

### 5.1 TTS Data Limitations

The TTS is a survey of the typical weekday travel patterns of private households. As a general rule it does not provide information concerning:

- Weekend and vacation travel.
- Commercial travel (goods movement, couriers, salesmen, taxi drivers, emergency vehicles, etc.)
- Travel by visitors staying in hotels.
- External and through travel from households outside the survey area.

Other sources of information must be used in order to estimate the amount of travel associated with each of these components of total daily and annual travel.

The TTS is also of limited value in addressing the transportation implications of special generators and associated events (e.g.: the CNE, sports events, concerts, etc.). The TTS may be able to provide information on background traffic levels but the trips actually associated with the facility or event must be estimated using other information.

The traffic zone containing Pearson International Airport according to the TTS is the most frequent destination for non home-based trips and is the $12^{\text {th }}$ most frequent destination zone for home-based other trips. However, the expanded total of 16,000 non work trips represents only a fraction of the daily movement through the airport of passengers, greeters and well-wishers.

While the TTS does contain a substantial amount of information on shopping trips, the peak demand at most shopping centres occurs on weekends and is seasonal in nature. These peaks are not adequately reflected in the TTS data. The TTS may provide useful information on background travel levels to be used in the planning of new plazas and as an indication of the average week day loading that shopping trips place on the road network. The analysis in Chapter 4 shows that shopping trips account for a relatively small proportion ( $5 \%$ ) of total daily auto travel and an even smaller proportion of peak period travel.

### 5.2 Other Home-based Trips

Other home-based trips, including shopping, account for $44 \%$ of total daily vehicular trips (excluding walk, cycle and school bus). Population based trip production rates can be used to predict trip productions at the home end with a reasonable degree of confidence. This approach is taken in both the full and simplified GTA models. The problem is in selecting appropriate zonal factor, or factors, on which to base forecasts of trip attractions. Retail floor area can be used as a predictor for shopping trip attractions but the previous analysis shows that shopping trips only account for $5 \%$ of total daily automobile use and $6 \%$ of local transit use. Given the significance of shopping, relative to the other trip purposes, and the discussion at the end of the previous section, the development of a separate trip generation model for shopping trips may not be justified.

In the development of the full GTA model it was concluded that zonal population was the best predictor of non work and non school a.m. peak period trip attractions. Employment and a combination of population and employment were also tested. Planning district (municipal) based average trip attraction rates are
applied at the traffic zone level to obtain spatial variability. Trip distribution is performed using the "Fratar" technique.

In the simplified GTA model, the existing distribution of trips is factored to match the change in population at the home end. The same approach as is used to forecast home-based school trips in both the full and simplified GTA models.

In the absence of a proven alternative either of the above approaches can be adapted for application to the p.m. peak or on a total daily basis. Both models use a seeding procedure to eliminate zeros from the observed TTS data thus enabling the factoring procedures to be applied in areas that do not currently have any population.

### 5.3 Non Home-based Trips

Figures 4.1(a) and (c) show that non home-based trips account for $21 \%$ of daily automobile travel and $10 \%$ of daily transit trips. Table 5.3(a) gives a further breakdown of the total non home-based trips by all modes.

Table 5.3(a) - Non Home-based Trip Categories

|  | Daily Trips |  |
| :--- | ---: | ---: |
| $1^{\text {st }}$ trip to work or last trip from work | 619,753 | $32 \%$ |
| Other trips to/from work | 401,220 | $21 \%$ |
| Non work related trips | 927,037 | $48 \%$ |
| Total NHB | $1,948,011$ |  |
| $2^{\text {nd }} \&$ subsequent home-based work trips | 102,202 |  |
| Total incl. second HBW trips | $2,050,213$ |  |

Many of the first trips to work and last trips from work are likely the result of combining a trip to or from work with other trip purposes forming a series of linked trips that start at home and finish at work or vice versa. The way work trips are usually modeled is to assume that all trip productions occur at the home location and trip attractions at the work end in effect substituting a single home to work trip for a series of linked trips. Table 5.3(b) shows the effect this substitution has on total vehicle-km of auto travel.

Table 5.3(b) - Total Daily First/Last Trips To/From Work

| Matrix Definition |  |  | Selection Criteria |  | Trips | Km of travel * |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | From | To | Origin Purpose | Dest. Purpose |  | Total | Mean |
| (1) | Origin | Destination | Home | 1st Work | 1,540,473 | 26,968,496 | 17.5 |
| (2) | Origin | Destination | Not home | 1st Work | 203,592 | 2,642,550 | 13.0 |
|  | Estimated total daily travel to work |  |  |  | (1)+(2) | 29,611,046 |  |
| (3) | Home | Destination | All | 1st Work | 1,745,203 (a) | 30,173,914 | 17.3 |
| (4) | Home | Usual Work | All | 1st Work | 1,687,317 $\quad$ (b) | 27,006,676 | 16.0 |
| Simulated total daily travel to work |  |  |  |  | (4)* ${ }^{*}(\mathrm{a}) /(\mathrm{b})$ | 27,933,181 |  |
| (5) | Home | Origin | Not home | 1st Work | 203,967 | 1,914,285 | 9.4 |
| (6) | Origin | Destination | Last work | Home | 1,429,390 | 24,975,800 | 17.5 |
| (7) | Origin | Destination | Last work | Not home | 336,292 | 4,371,060 | 13.0 |
| Estimated total daily travel from work |  |  |  |  | (7)+(8) | 29,346,860 |  |
| (8) | Origin | Home | Last work | All | 1,767,067 (d) | 30,272,866 | 17.1 |
| (9) | Usual work | Home | Last work | All | 1,708,669 (e) | 27,216,190 | 15.9 |
| Simulated total daily travel from work |  |  |  |  | (9)** ${ }^{*}$ )/(e) | 28,146,371 |  |
| (10) | Destination | Home | \|Last work | Not home | 336,974 | 3,743,595 | 11.1 |

* Minimum distance paths on the 1996 emme/2 road network

Daily travel to work is broken down into two components; those trips that start at home (1), and those that start at other locations (2). It is assumed, in the simulation, that travel to work will occur only between the home location and the usual place of work. The total number of trips in the home to usual place of work matrix (3) has been adjusted by applying a global factor to match the total observed first work trip destinations matrix (4). The difference occurs because not all people have a usual place of work. It is assumed that the work trip production and attraction rates used in a simulation model will be based on all first trips to work, not just those to the usual place of work. The resulting total travel distance is 1.7 million $\mathrm{km}(6 \%)$ lower than the observed total. The difference, however, is due primarily to the substitution of the usual place of work for actual work destination, which increases mean home to work trip length by $8 \%$. Substituting home for non home locations reduces the net change in mean trip length by only $1 \%$.

The trips and travel totals do not include the other home-based component of linked trips to work since they would normally be included in the other home-based component of the model. No attempt has been made to identify home to work trip "chains" in the TTS database. The home to origin link for non home to work trips (5) is included in the table as an approximation to show the relative significance of that component of total daily travel.

Rows 6 through 10 provide a similar comparison for last trips from work. The discrepancy between estimated and simulated travel daily distances is 1.2 million km (4\%). Approximately $20 \%$ of the last trip from work are non home-based compared to $12 \%$ of the first trips to work.

Table 5.3(b) includes trips in the GTA and Hamilton-Wentworth made by non residents of that area, hence the minor variations in trip totals and possible differences from other tables in this report.

The second sub-component of non home-based travel shown in Table 5.3(a) is trips to and from work other than the first trip of the day to work and the last trip of the day from work. This sub-component includes trips made at lunch time and business travel between work locations. The average trip length is short with a median straight line distance of 7 km . In total this sub-component therefore accounts for about $3 \%$ of total daily auto travel. The trips occur predominantly in the off peak period and can likely be ignored for most design purposes. A global adjustment factor can be applied, if required, for other purposes such as fuel consumption and air quality standards.

The third sub-component of non home-based travel consists of trips that do not relate to work at either end. This is the most difficult component of daily travel to simulate because of the absence of an obvious trip generation predictor for either end of the trip. The approach taken in the existing simplified and full GTA models is to include these trips with home-based other trips using population as the predictor (both ends in the full model, origins only in the simplified model). In the short term it is recommended that the same approach be adopted for p.m. peak and all day modeling but that the testing of alternative approaches, such as continuum modeling, be a high priority for further research. This sub-component accounts for about $10 \%$ of total daily auto travel ( $48 \%$ of $21 \%$ ).

The number of subsequent home to work trips and previous to last work to home trips is included in Table 5.3(a) because, although home-based, they are not usually included in home-based work trip rates. These trips differ significantly in characteristics from first trips to work/last trips from work both in the time of day they occur and trip length. The median trip length is 5 km . The amount of automobile travel involved is less than $0.5 \%$ of the daily total. It does not really matter whether these trips are included in home-based work, home-based other, non home-based or ignored provided that the trip generation and distribution components of the model are consistent.

### 5.4 Over Simulation of Peak Period

There is evidence that the use of TTS data, together with existing network simulation techniques, can lead to over representation of the peak period and peak hour traffic volumes with a corresponding under representation of off-peak travel. The existence of the problem may have been masked in the past by the under representation of non work trips. The problem can be attributed in part to the trip assignment technique currently used in EMME/2 and most other traffic simulation software packages. An underlying assumption is that the network is in a steady state condition over an extended period of time sufficient for
the rates of flow represented by the trip matrices to extend throughout the network. In real life steady state conditions never exist. Trips take different amounts of time to reach different parts of the network. Queuing situations are developing and dissipating all the time. Traffic volumes will be over represented if the amount of traffic still in transit in the system is greater at the end of the simulation period, than at the beginning, as is the case in the a.m. peak period model.

The scope for distortion depends on trip lengths. The median trip length, about 5 km for auto drivers, is not a good reference because it is long trips that produce most of the load on the network. Approximately $50 \%$ of total traffic volume are created by the $14 \%$ of trips that are over 21 km in length (straight line distance). Cordon and other on-street counts reflect the composition of the traffic flow, not the universe of trips. For example a select link assignment of TTS data to the EMME/2 road network produced a median trip length of 24.2 km (minimum distance path on the network) for auto driver trips crossing the Toronto boundary compared with a median of 5.4 km for all auto driver trips. This is one reason why many simulation models tend to over simulate volumes on freeways relative to other roads. The problem is most noticeable in the a.m. peak, covering the transition from lightly loaded conditions at 6 a.m. through the period of peak traffic generation, the congestion effects of which are not fully dissipated until well after the peak period of trip generation is over. An advantage of simulating the p.m. peak period is to reduce the transitional effects. The p.m. peak extends over a longer period of time and represents less of a contrast relative to traffic volumes before and after the peak.

The ideal solution to the problem would be to use a real time simulation in which each vehicle is moved through the system in small increments of time with facility to represent queue delays at points of congestion. EMME/2 does not currently have this capability nor is it practical since individual departure times would have to be predicted for every trip. The practical alternative is to apply adjustment factors to either the trip table or the assigned link volumes. The choice of appropriate adjustment factors is complicated due to the fact that every link in the network is unique with respect to its relationship to specific origins and destinations and the time it takes to reach that particular link. It is suggested that the adjustment be incorporated into the peak hour factor as discussed in the next section.

### 5.5 Peak Hour Factor

Both the full and the simplified GTA models use a 3-hour peak period for mode split calculations and 1hour road capacities for trip assignment. Reasons for basing the mode split calculation on the 3-hour volumes include the amount of data available and clear evidence that trip start time is related to mode of transport. Within the 3-hour period GO Rail has the most pronounced peak ( $80 \%$ of the 3-hour total occurs in the peak one hour) and road travel the lowest ( $40 \%$ of the 3 -hour total occurring in the peak one hour).

The two models differ slightly in the conversion from 3-hour to 1-hour volumes. The full GTA model uses a global factor of 405 applied to the 3-hour trip matrix. The simplified model produces a 3-hour trip assignment with differential factors applied to the 1-hour link capacities to obtain a 3-hour "capacity". The same factors (. 35 for freeways, .4 for arterials and .5 for local streets) are applied to the link volumes after assignment if peak hour link volumes are required as an output.

A third alternative would be to apply O-D specific conversion factors to the trip matrix. Figure 5.5(a) shows the relationship between the peak hour and peak 3-hour periods based on trip start times for auto drivers as given in the TTS database. The peak periods have been taken as 6:00 to 8:59 a.m. and 3:30 to 6:29 p.m. The peak hours are 7:45 to 8:44 a.m. and 4:30 to 5:29 p.m. The peak hour factor for trips longer than 20 km is less than one third of the 3-hour total because the peak hour for longer trips starts at about 6:45 a.m. (Figure 5.5(b)). The factor for short trips is also slightly under stated at $60 \%$ because the peak hour for trips of less than 5 km does not start until 8 a.m. The p.m. peak hour is clearly far more consistent in that there is little variation with trip length in either the time at which the peak hour occurs or the factor relative to the peak 3-hour total. A global factor would appear to fit the p.m. peaking characteristics better than it does the a.m. peak. A factor in the .35 to .4 range is consistent with the observed ratio for short trips and allows for some disbursement of longer trips relative to the concentration of start times as discussed in Section 5.2. In the a.m., a factor of 0.3 or less applied to long trips or assigned volumes on freeways can be justified on the basis of the over representation discussed in Section 5.2.

Figure 5.5(a) - Peak Hour to Peak Period Auto Driver Trip Ratios

Figure 5.5(b) - Peak Hour to Daily Trip Ratios by Trip Length

### 5.6 P.M. Peak Simulation Models

Higher hourly traffic volumes and a longer peak period than in the a.m. dictate that forecasts of p.m. peak travel should be used for the planning of roads. In most areas the highest demand on public transit is in the a.m. because school trips tend to be made at the same time as work trips in the morning but are made earlier than work trips in the afternoon. In order to adapt the existing GTA model (both full and simplified) the following changes are recommended as first steps for development and testing.

- The peak period be defined as 3:30 to 6:29 p.m. for the extraction of TTS data
- It is essential that the reported TTS non work and non school trip rates be adjusted to correct for under reporting. The use of global factors, stratified by mode and trip purpose, may be sufficient for most planning purposes.
- Work and school trip generation need to be reversed, i.e., population based trip rates should be used to calculate trip destinations and, in the case of work trips, employment based rates used to calculate origins. The origin work trip rates and peak period factors need to be based on all last trips from work regardless of destination purpose. Destination rates from TTS will need to be adjusted to reflect the non home component.
- Home-based other and non home-based other (not work or school) trips continue to be treated as a single purpose using trip generation rates based on population. Those rates should exclude all work origins and destinations. The simplified GTA model differs from the full GTA model in that non work and non school trip generation is based on changes in population at the origin end. For the p.m. peak it will be desirable to separate the trips with home as their destination and apply the same procedure with population-based trip destination rates. The full GTA model uses population to forecast both origins and destinations, so a single category and matrix may suffice.
- Mode split factors and formulae need to be re-calibrated for the p.m. peak.
- A global factor may be used to convert peak period auto trip tables, or assigned traffic volumes, to 1 -hour totals. An initial value of .38 is suggested pending further validation against cordon counts.

One might expect a p.m. peak model to be less reliable than an a.m. peak model because of the difficulties in forecasting non work and non school travel and the greater variation in day to day behaviour. The information contained in this report should help to address this problem. Although more people go directly to work in the morning than go directly home in the evening the proportion of direct to home travel is still high at about $80 \%$ (compared to $88 \%$ in the morning). Simulating the p.m. peak does have advantages relative to the a.m. particularly in regard to the uniform spatial and time distribution of trips before, during and after the peak period.

### 5.7 24-hour Simulations

The simplest approach to forecasting 24-hour travel is to apply 24-hour adjustment factors, stratified spatially and/or by road type, to one of the peak period (a.m. or p.m.) simulations. While adequate for global forecasts of vehicle-km of travel etc., such factoring is not likely to produce reliable estimates of usage on specific facilities.

Another option for simulating total daily travel is to have separate models for each time period (a.m. peak, mid-day, p.m. peak, evening and night) and to combine the results to give total traffic volumes. The primary advantage of this approach, relative to a single 24-hour model, is that variations in transit levels of service and road congestion by time of day on different parts of the network can be taken into account in the mode split and assignment procedures. The disadvantages are the increased complexity and the need to address the issue of trip start times and peaking factors in considerable detail.

A single 24-hour model is recommended as a practical alternative capable of generating facility specific traffic volumes that are realistic. The model would likely have the same trip components as recommended for a p.m. peak model. Mode split calculations should be based on peak period transit level of service since over $80 \%$ of all transit trips are work or school related.

An appropriate factor, or factors, will need to be selected to convert 1-hour capacities to 24-hour capacities, or conversely 24 -hour trip tables to 1 -hour volumes. A factor close to, but less than the observed peak hour proportion of daily volumes, is recommended as appropriate. The selected number can be a design hour standard or target. Figure 5.5 (b) shows that a value of $9.5 \%$ would reflect the average conditions across the GTA network in 1996. A lower target (say 9\%) might be appropriate for the future given the expected continuation in the trend towards an increase in the proportion of discretionary travel relative to peak period work and school related travel.

## APPENDIX - Definitions Used in Cordon Count Comparisons

## Screenline Definitions

## Toronto

- Peel boundary
- York boundary
- Durham boundary
- Humber River between Lake Ontario \& Steeles Avenue
- Highway 401 between Peel \& Durham boundaries
- Uxbridge Rail sub-division from Steeles Avenue and extended south to Lake Ontario

Peel

- Toronto boundary
- York boundary
- Halton boundary
- QEW between Toronto and Halton boundaries
- Highway 401 between Toronto and Halton boundaries
- Credit River between Lake Ontario and Highway 401

## York

- Peel boundary
- Durham boundary
- South York Cordon as defined in 1995 York Region Cordon Count Report

## Durham

- York boundary
- Highway 401 between Toronto and the east boundary of Oshawa
- Highway 2 between Toronto and the east boundary of Oshawa
- West boundary of Whitby

The same boundary (e.g. Peel/York) may be counted in two different locations depending on which agency is taking the counts. The links in the EMME/2 network have been selected to represent the locations as accurately as possible but do not always provide an exact match.

## Time Period Definitions

## TTS data

- Morning peak 6:00 to 8:59 a.m.
- Midday 9:00 a.m. to 3:29 p.m.
- Afternoon peak 3:30 to 6:29 p.m.
- Evening 6:30 to 8:59 p.m.

## Cordon Count Data

- Morning peak 6:15 to 9:15 a.m.
- Midday 9:15 a.m. to 3:45 p.m.
- Afternoon peak 3:45 to 6:45 p.m.
- Evening 6:45 to 9:15 p.m.

## Vehicle/Mode Definitions

TTS - Auto driver
Cordon count - Private vehicles
